## 1 Service Description Overview

The reject-relay service allows systems to relay back the fact that a contract was rejected by another party.

## 2 Abstract Information Model

The reject-relay service has one interface exposed which allows for systems to relay the fact that some other system rejected the offered contract. This interface is `rejectRelay`.

### 2.1 RejectRelay

`RejectRelay` is used to relay a rejection of a contract back to the system which made the contract offer in the first place. Contracts are an agreement between two systems to trade some data for currency. If the input is correctly formatted the contract should be dropped by the system which made the contract offer. If the input is incorrectly formatted an error will be thrown.
